

SQL

Subquery and Its Types

Pradeep M
@pradeep-m-analyst

1

Subquery

A subquery in SQL is like a query inside another query.

It's used to fetch data from the database based on the result of another query.

2

Types of Subqueries

There are two main types of subqueries:

- Correlated Subquery
- Non-Correlated Subquery

3

Correlated Subquery

This is the most common type.

It depends on data extracted from the outer query.

3

Example

```
SELECT name  
FROM employees  
WHERE salary > (SELECT AVG(salary) FROM employees);
```

4

In this example, the subquery (**SELECT AVG(salary) FROM employees**) calculates the average salary of all employees.

The main query then uses this average to find employees who earn more than the average salary.

5

Non-Correlated Subquery

This type of subquery runs only once and does not depend on the outer query.

6

Example

```
SELECT e1.name  
FROM employees e1  
WHERE salary > (SELECT AVG(salary) FROM employees e2  
                WHERE e1.department = e2.department);
```

In this example, for each row processed by the outer query, the subquery calculates the average salary of employees in the same department.

The main query then compares the salary of each employee to the average salary of their department.

**I hope you find this
valuable! 🥰**

**A like from you would be a great
encouragement**
